

How to build the "Unicorn name" automation

How to create a new project

- 1 To begin the exercise, go to your **Studio Web** home page and click **Create New**.

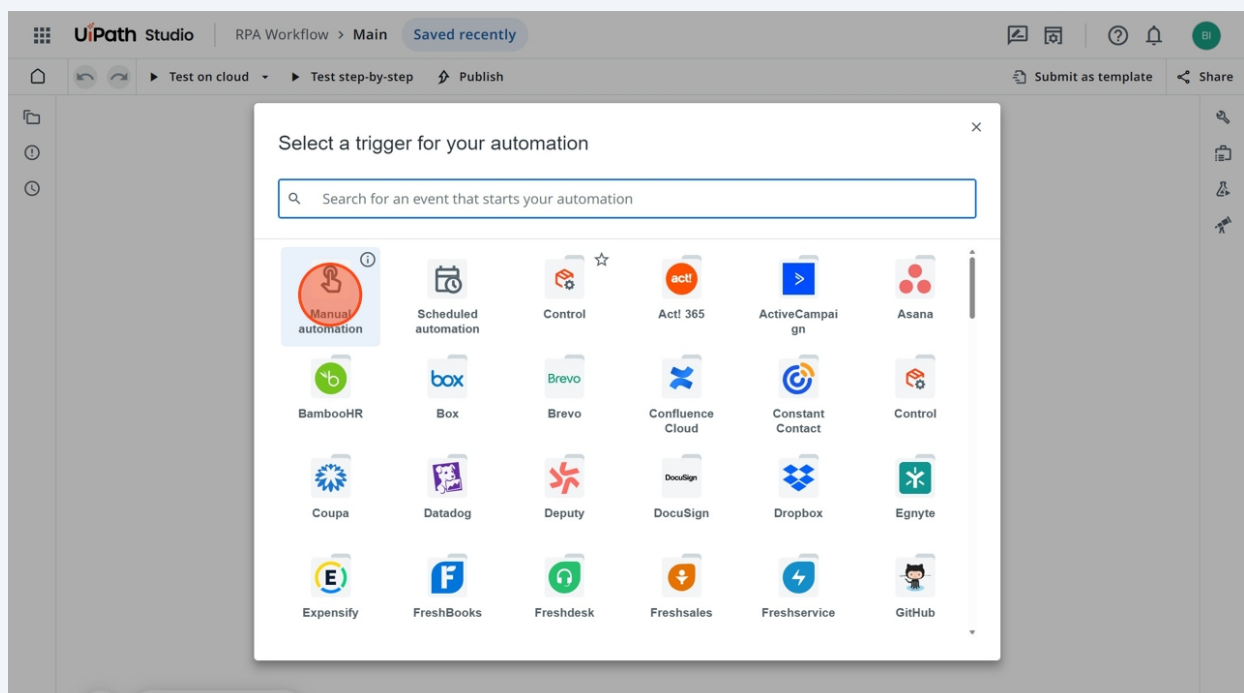

2 Since you'll be creating an automation, select **RPA Workflow** from the list.

3 Every **Studio Web RPA workflow** starts with a **trigger**, which we'll explain in the next step.

For this exercise, the automation will start **manually**.

What are triggers?

Triggers define *how* and *when* an automation starts. In Studio Web, there are three types:

1. Manual trigger

You start the automation yourself — usually by clicking **Run** in UiPath Assistant.

👉 *Best for testing or on-demand tasks.*

2. Time trigger

The automation runs on a set schedule (daily, weekly, etc.), like a calendar reminder.

👉 *Great for regular reports or daily checks.*

3. Event-based trigger

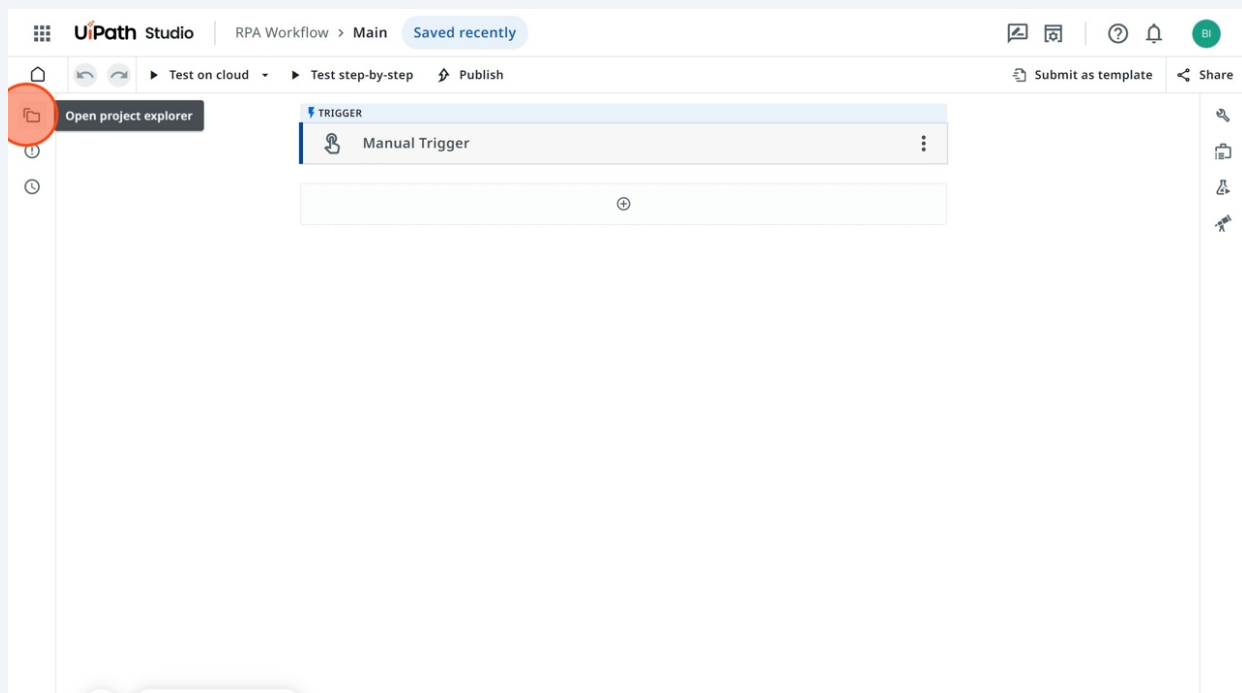

The automation starts automatically when something happens — like receiving an email or adding a new file to a folder.

👉 *Ideal for reactive tasks that need quick action.*

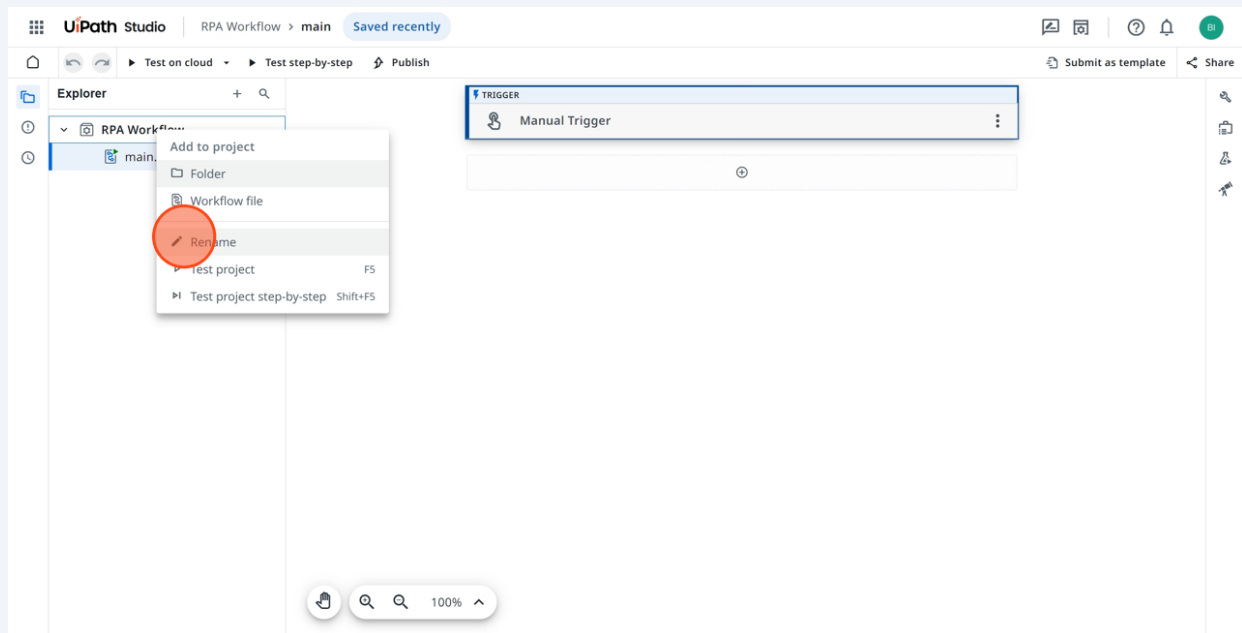

How to rename your project

4

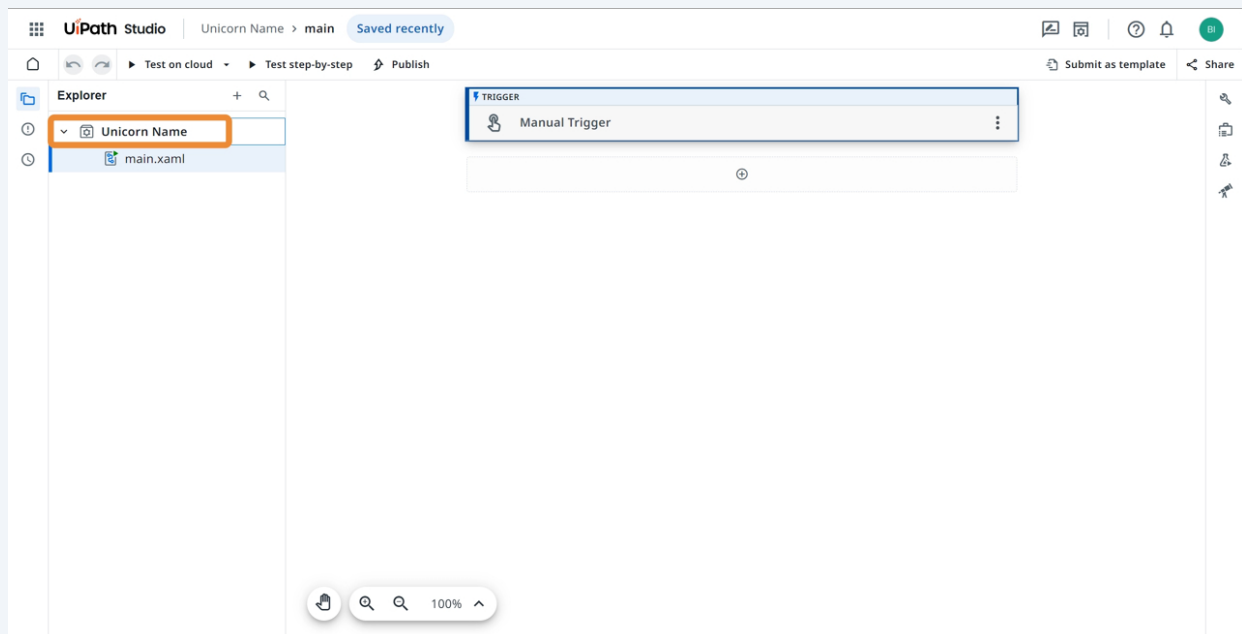

As a best practice, rename your project as soon as you create it. To do that, **open the project explorer**.

5 Right-click on RPA Workflow, and select **Rename** from the menu.

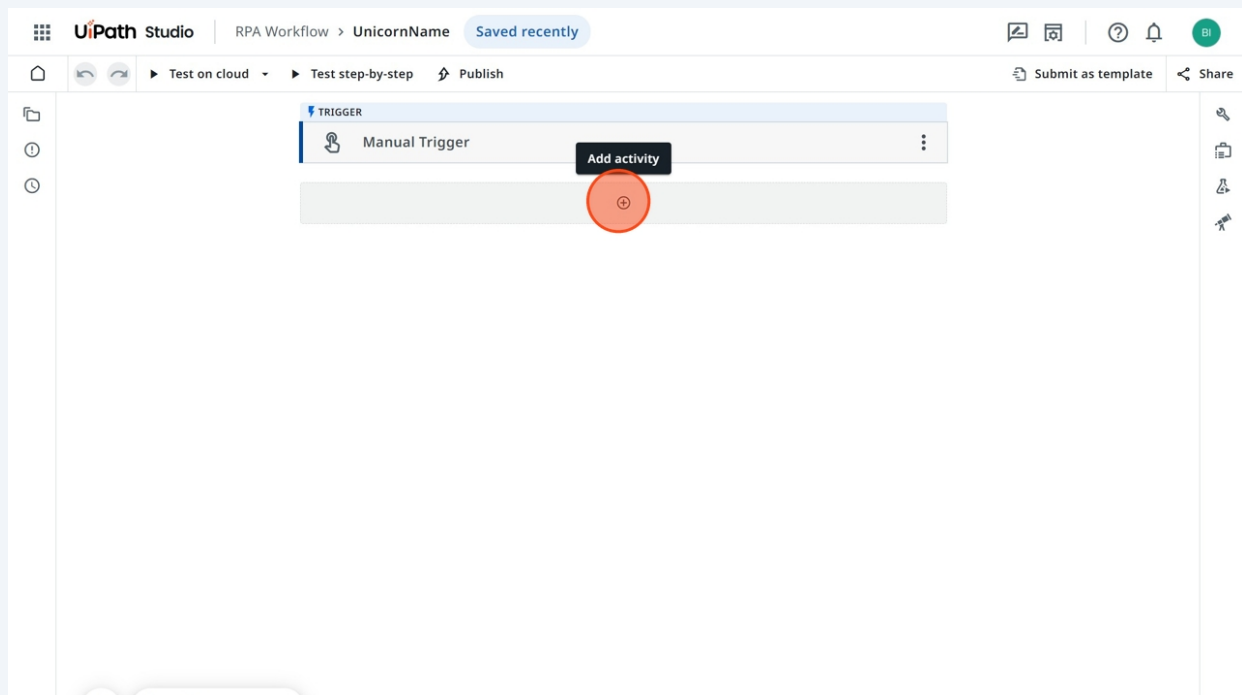

6 Name the project **Unicorn Name**.

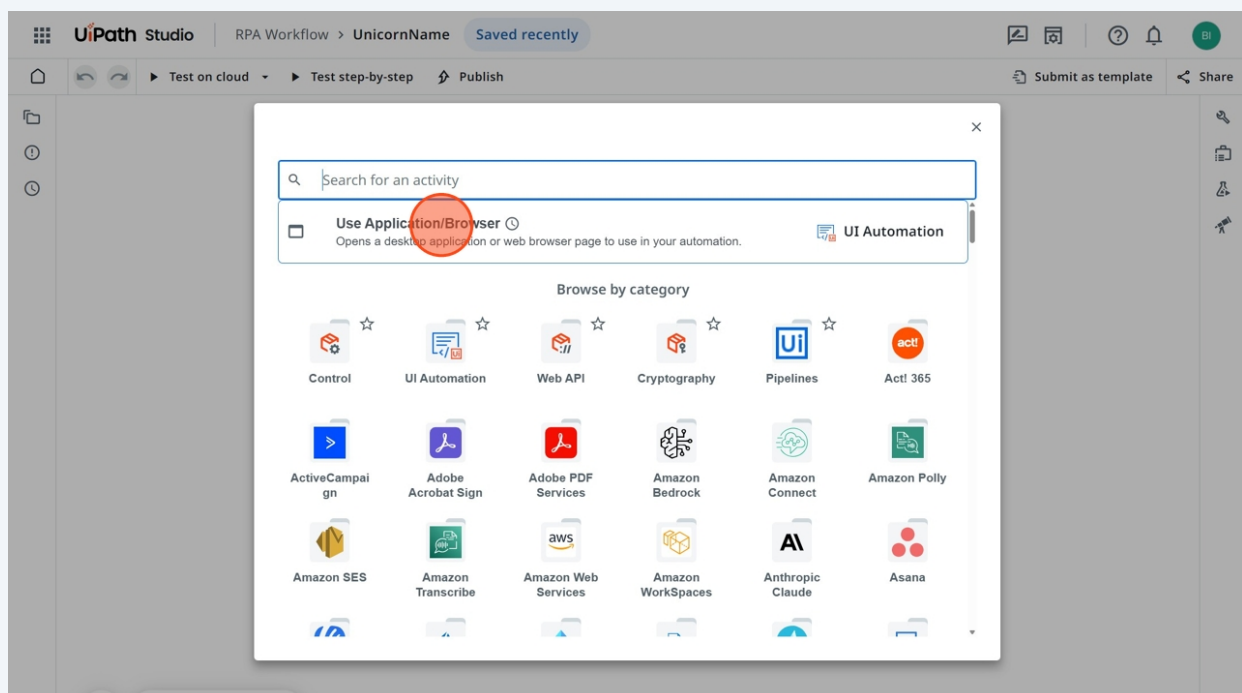

How to input data from a spreadsheet to a web form

7 Let's add the first activity, which tells the robot to use the **Unicorn Name** website.

To add a new activity, click the **plus (+)** button—this opens the **Activity Catalog**.

8 Search for and select the **Use Application/Browser** activity.

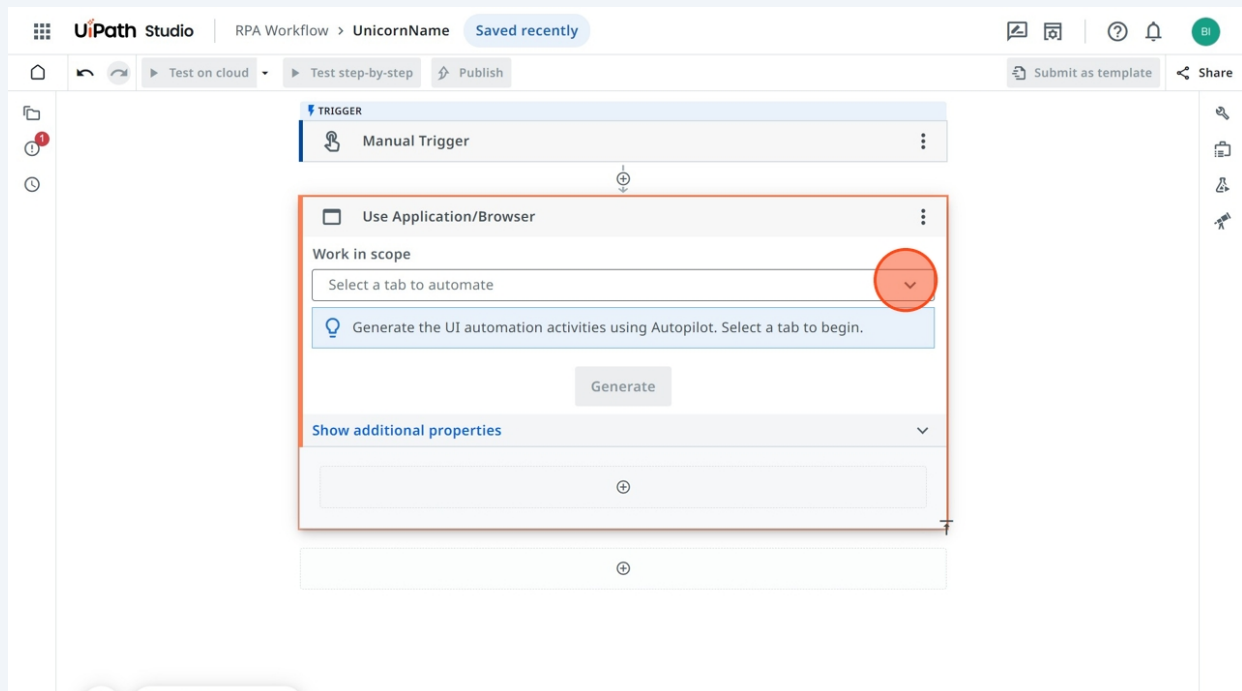

What does the "Use Browser" activity do?

The **Use Browser** activity tells the automation which website to work with. It opens a browser page (like Chrome or Edge) and creates a space where other actions — like clicking buttons, typing into fields, or extracting data — can happen.

Everything you want the robot to do on that web page is *nested inside* this activity.

9

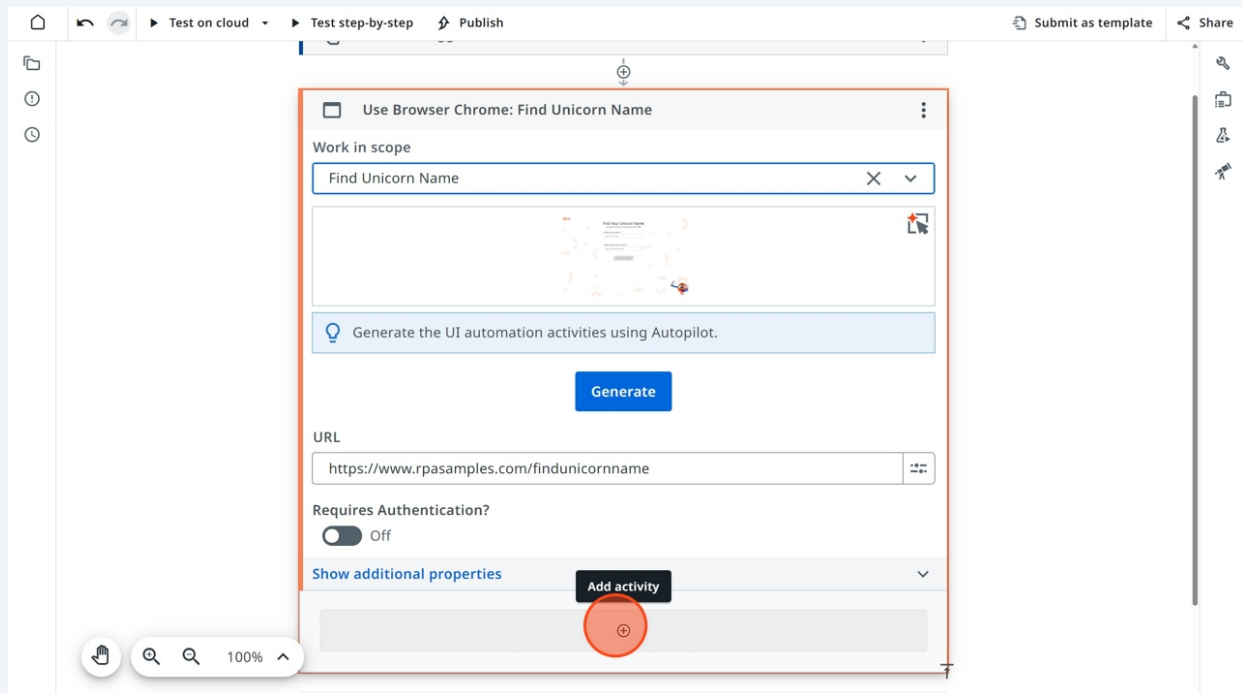

From the **Work in scope** dropdown, select the browser tab where you've opened the **Unicorn Name** website.

10

The next step is to **iterate through the spreadsheet**, allowing the robot to pick up each value.

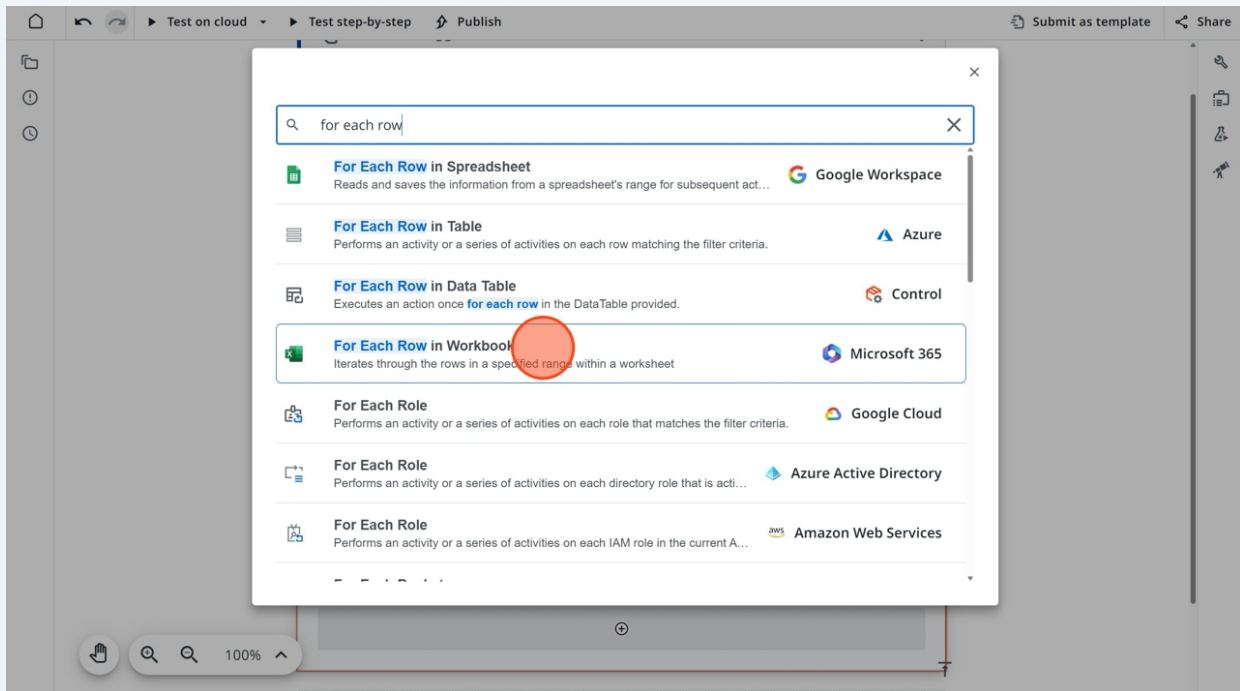

Click the **plus (+)** button inside the **Use Browser** activity to open the **Activity Catalog**.

11 Search for **For Each Row** in the Activity Catalog.

- If you're a **Microsoft 365** user, select **For Each Row in Workbook**.
- If you're using **Google Workspace**, select **For Each Row in Spreadsheet**.

We'll continue with the **Microsoft 365** option, but the configuration remains the same for both.

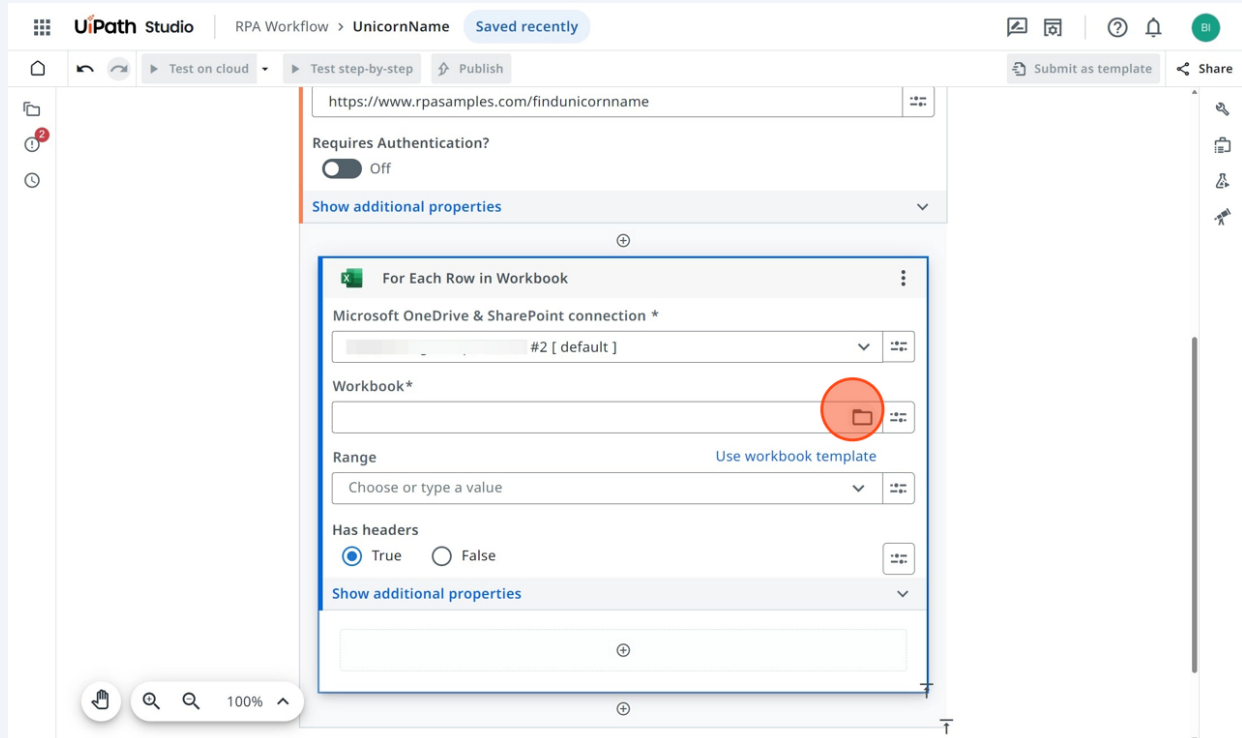

What does the "For Each" activity do?

The **For Each** activity tells the robot to repeat a set of actions for every item in a list — like going through each row in a table, each email in your inbox, or each file in a folder.

You place the steps you want to repeat *inside* the activity, and it will do them one by one for every item.

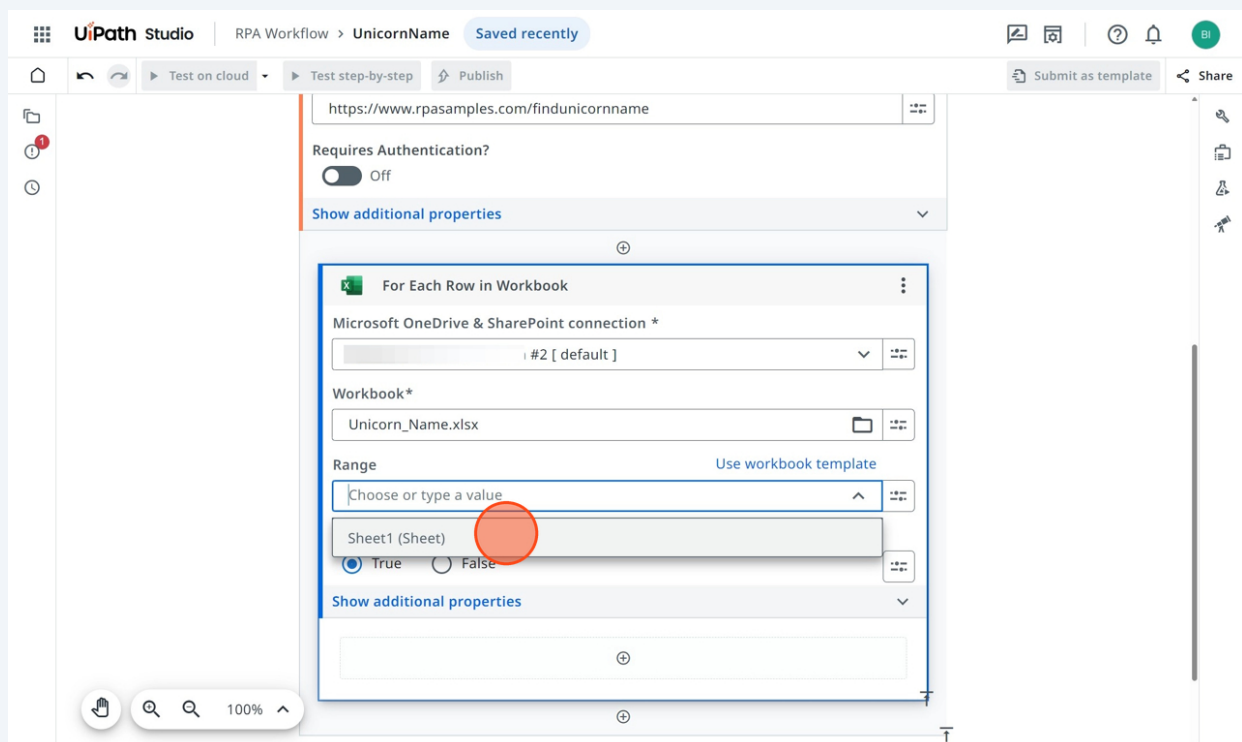

12

If you've completed the **Introduction to Automation** exercise, your connections should already be set up. All that's left to do is **select the workbook** containing the data for this exercise.

13

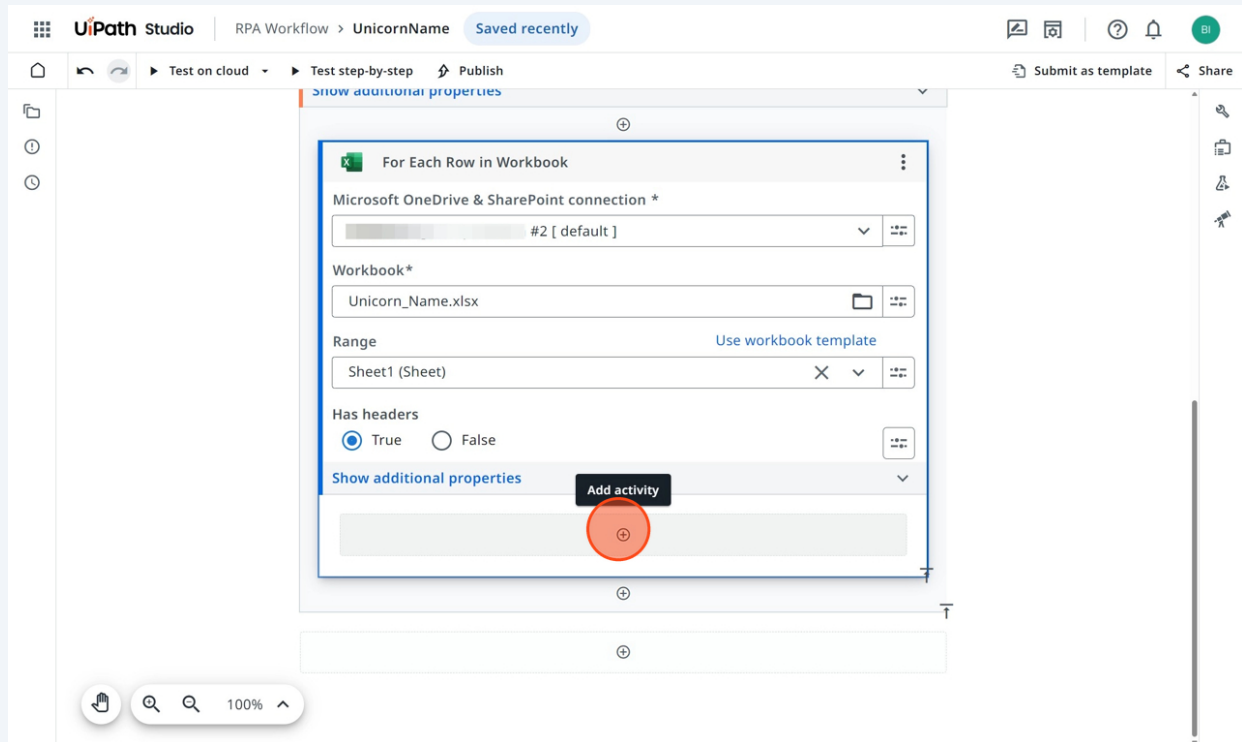

Select **Sheet1** from the Range options, and you are done with this activity.

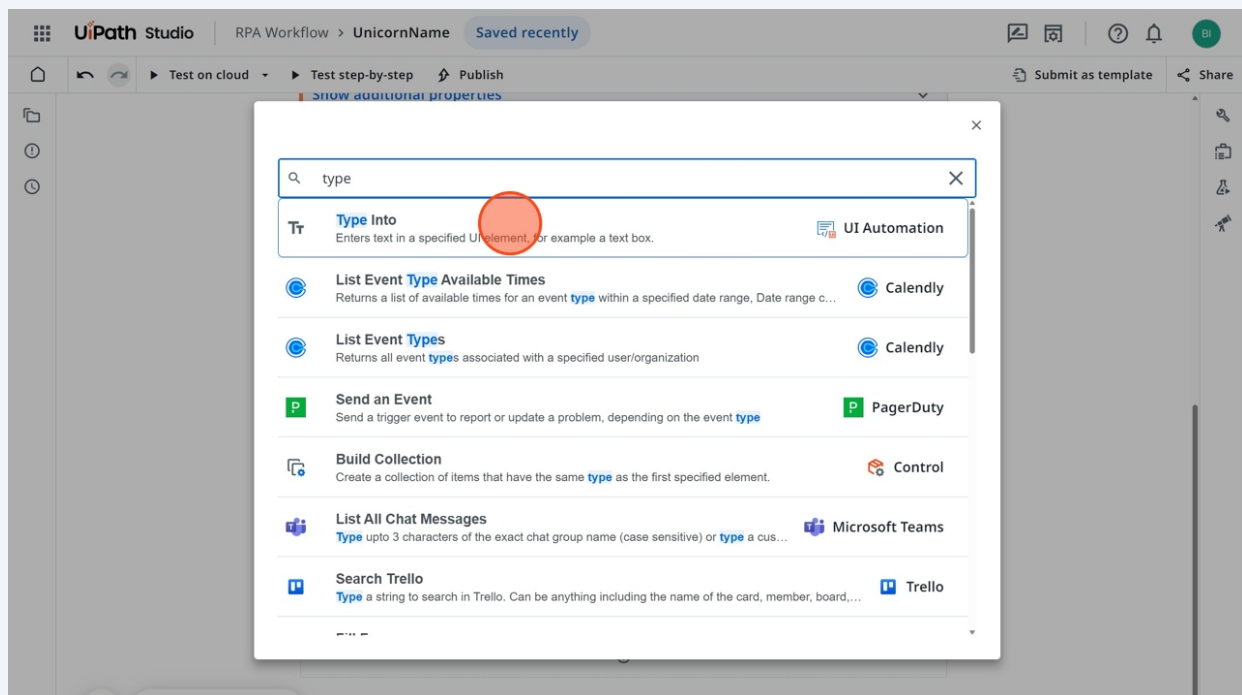

14

The first step in processing the spreadsheet is to type the name from the **Name** column into the **“What is your name?”** field on the form.

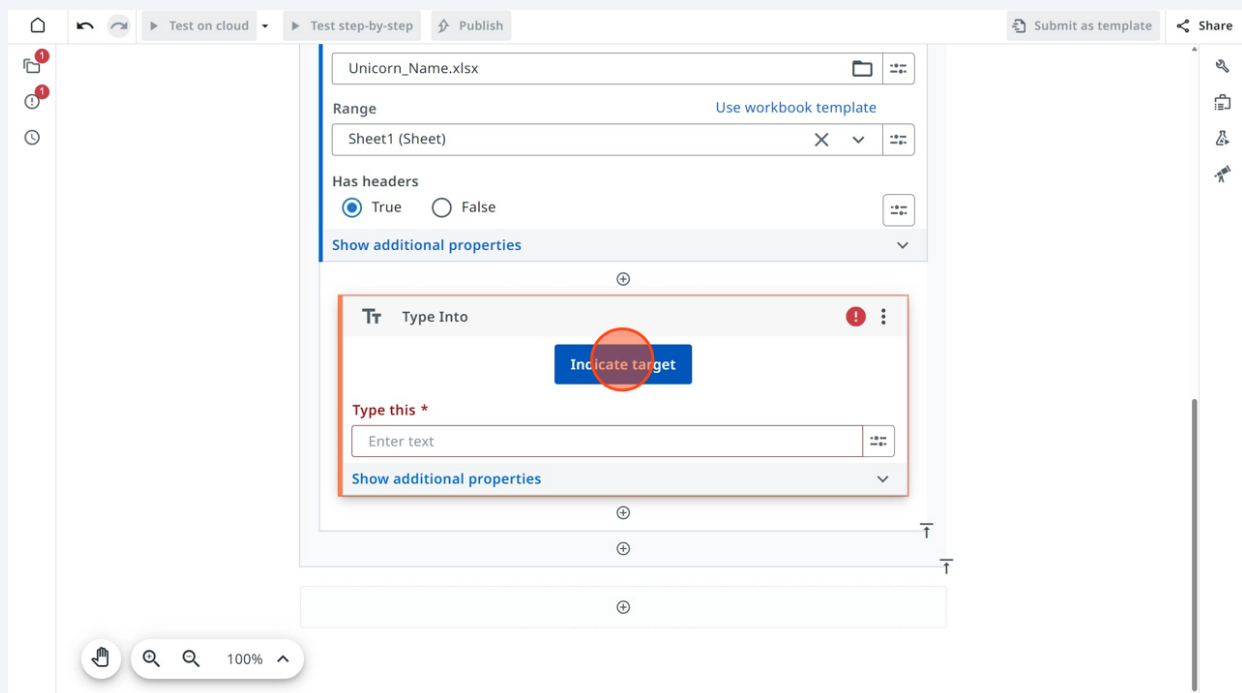

Open the **Activity Catalog** to add a new activity. Make sure to click the **first plus (+)** button—this ensures the activity is placed **inside the iteration**.

15 Select the **Type Into** activity.

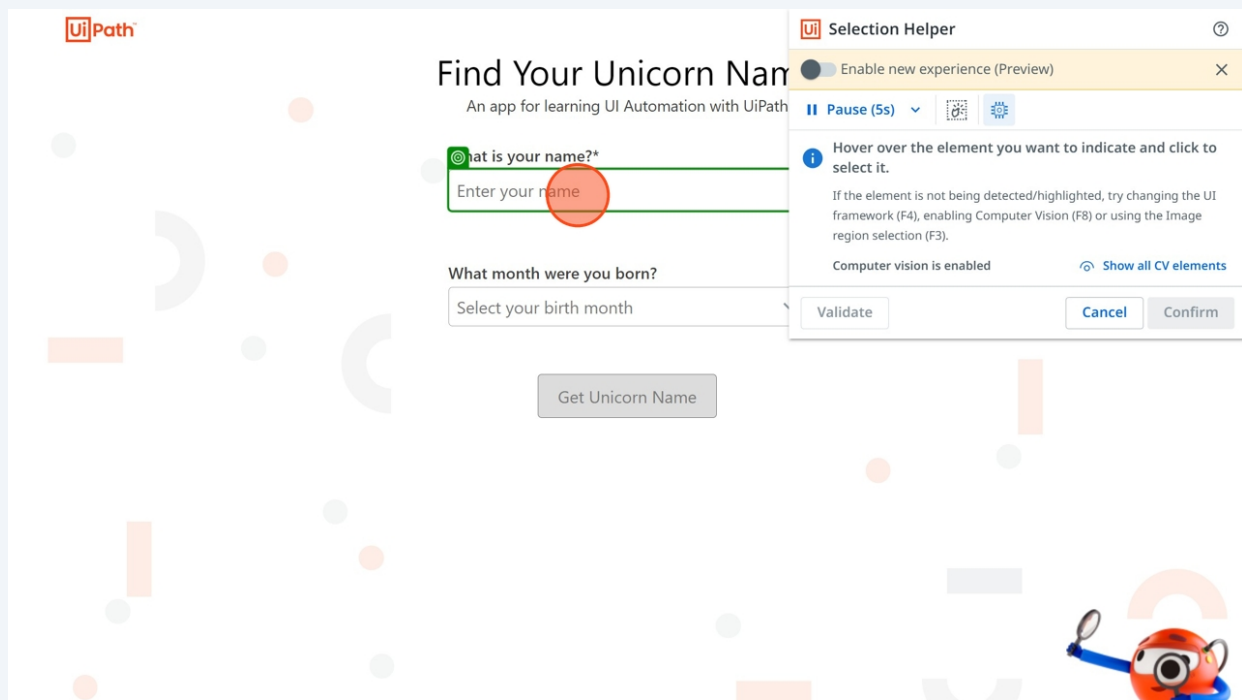

16 Now let's indicate the target.

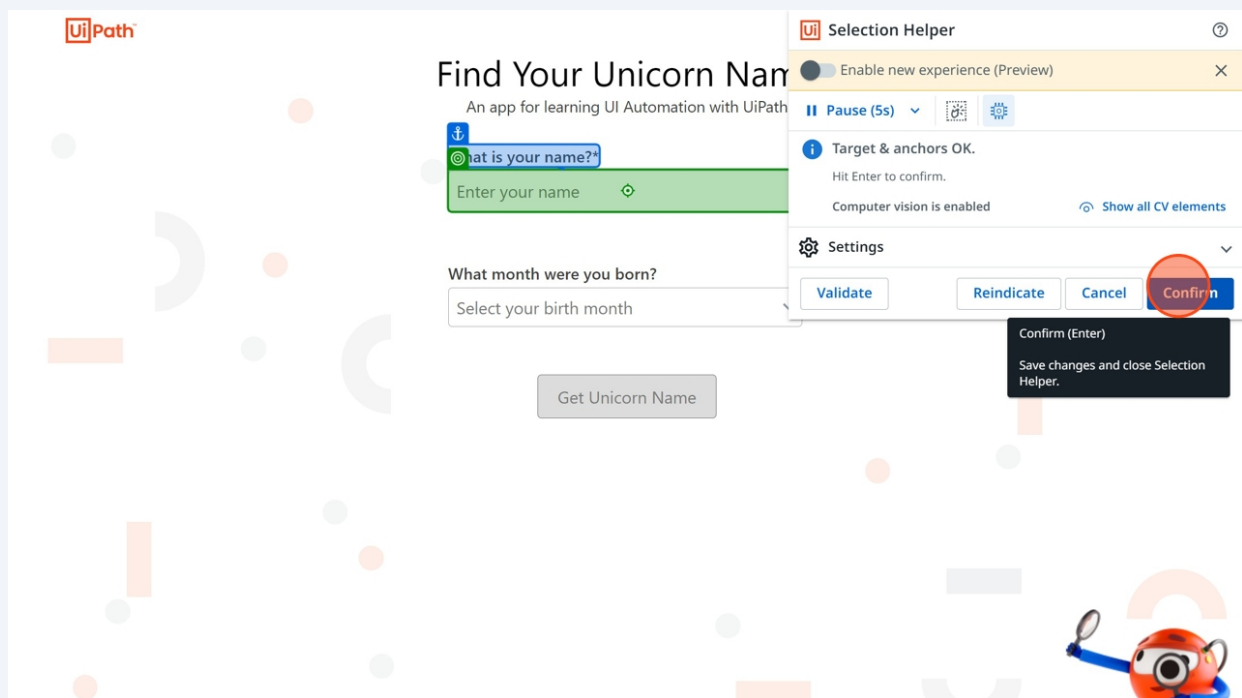

17

Click on the input field—it will be highlighted in **green**, indicating that the target was placed successfully.

18

The area highlighted in **blue** is the **anchor**, which was automatically detected. Click on confirm to return to the project.

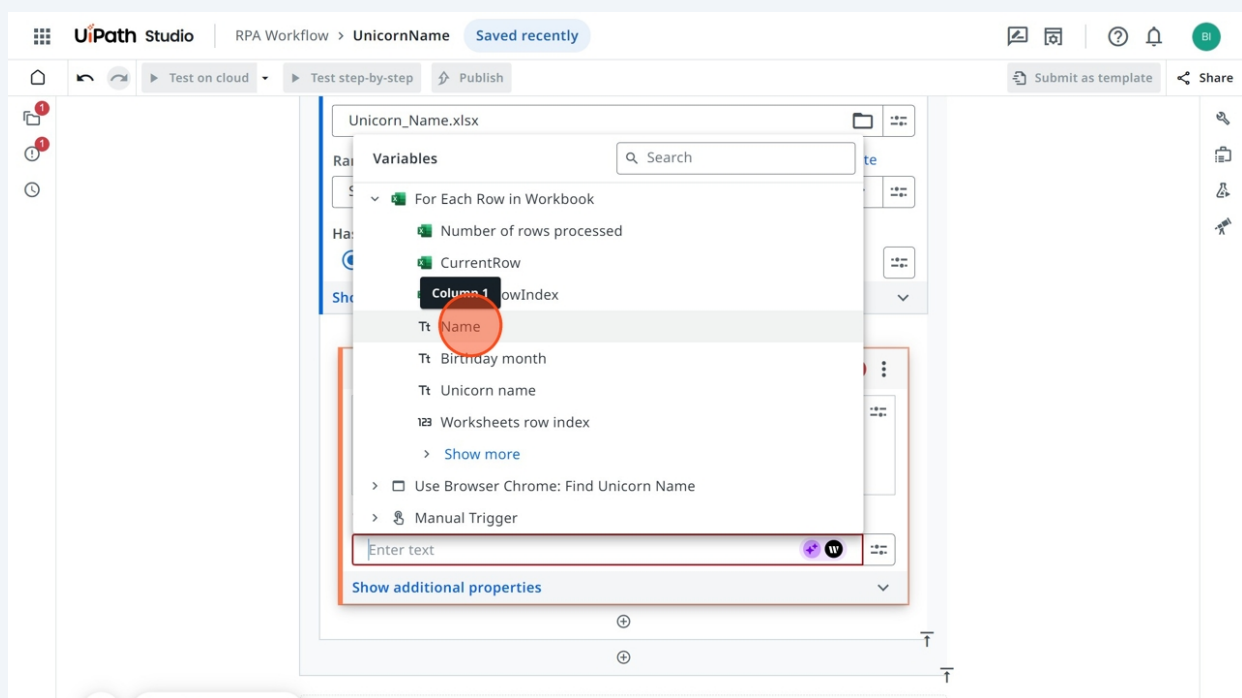

What are Target and Anchor?

When automating a web or desktop app, the robot needs to know **where** to click, type, or get data. That's where **Target** and **Anchor** come in.

- **Target** tells the robot *what* element to interact with (like a button, field, or label).
- **Anchor** helps the robot find the right spot by using a nearby, stable element — especially useful when the target moves or looks similar to others.

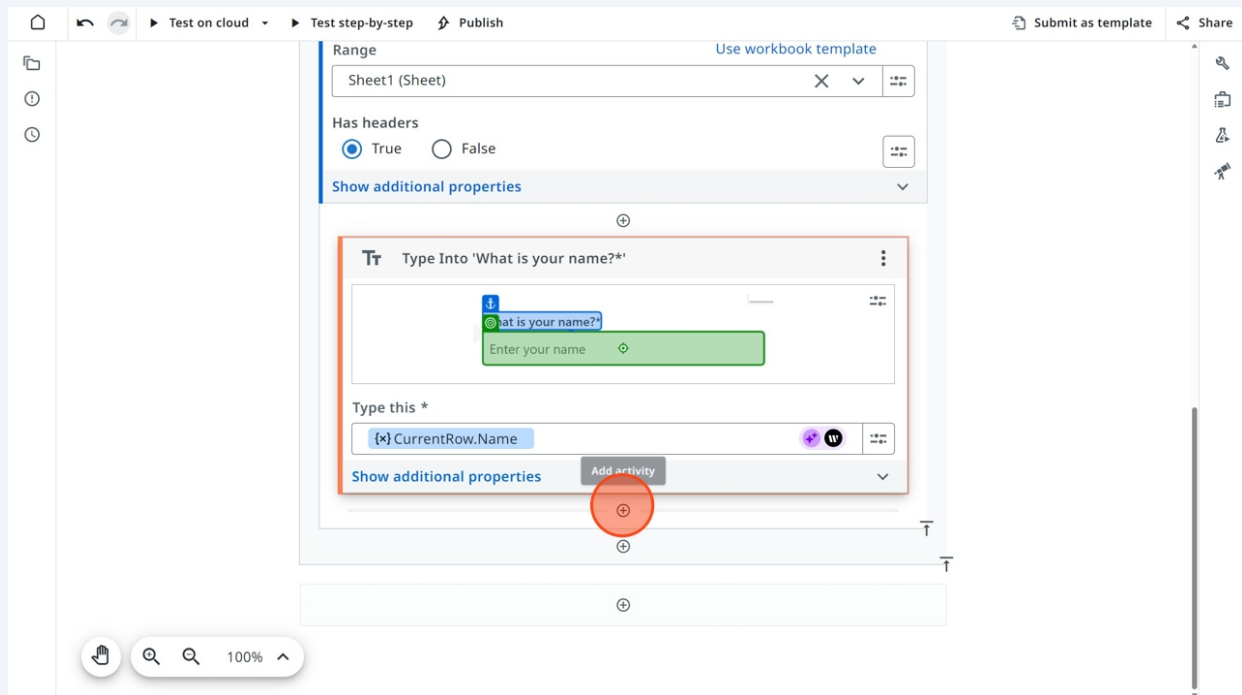

19

Since we're typing values from the **Name** column, select the **Name** variable found under **For Each Row in Workbook**.

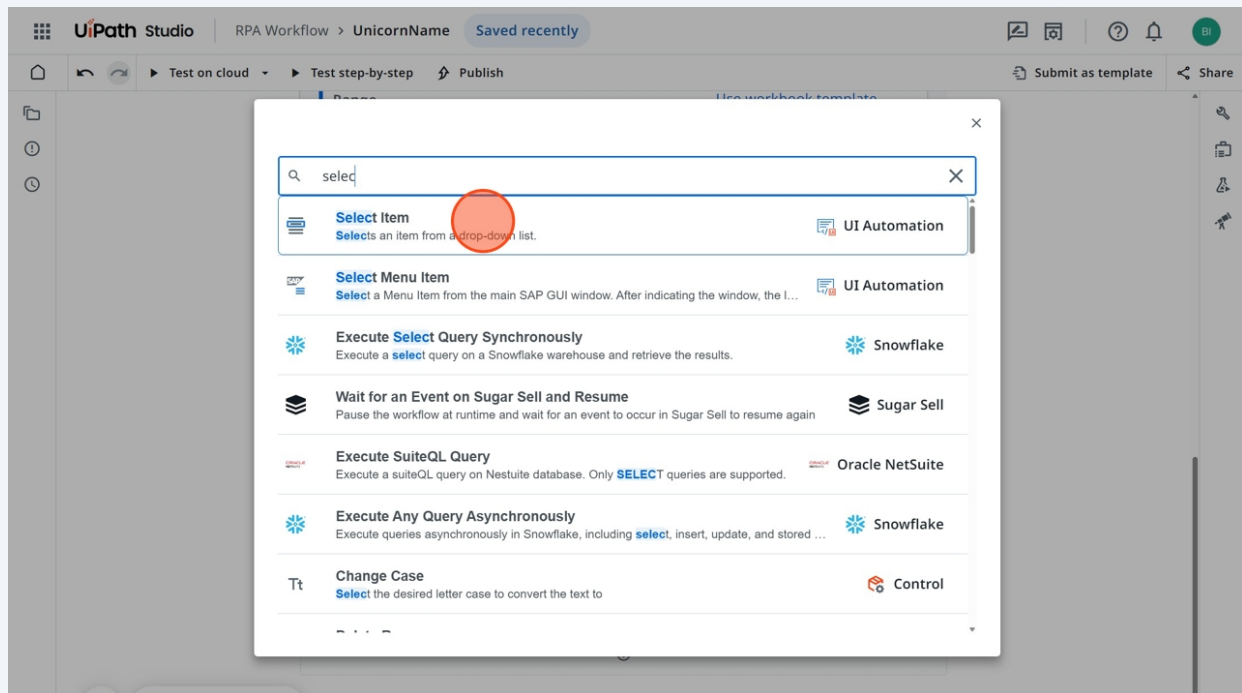

20

Now let's add another activity to **select the birth month** from the dropdown menu.

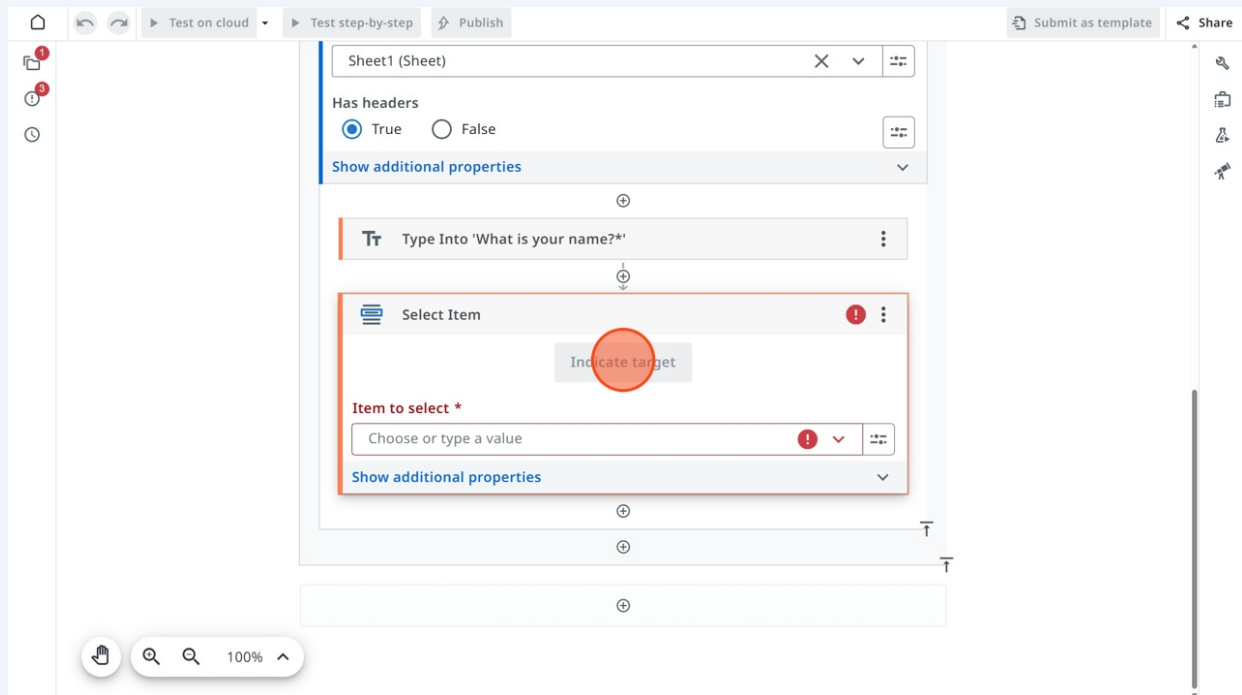

21

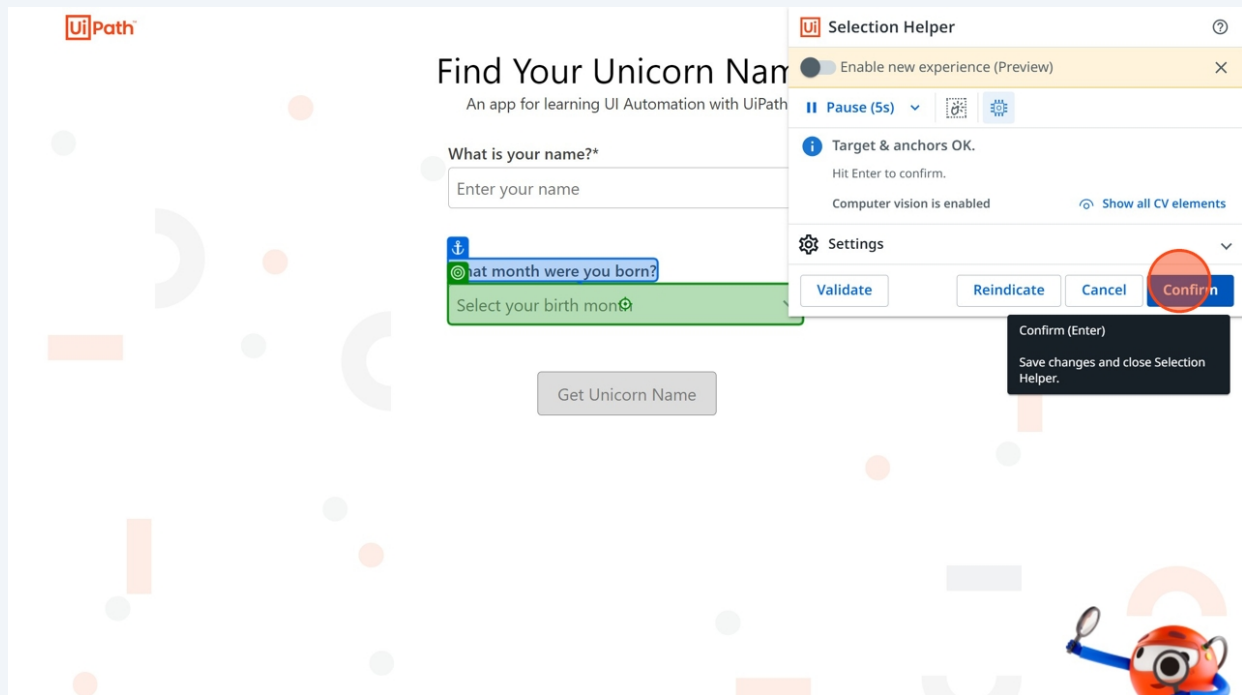

Add the **Select Item** activity.

22 Click **Indicate target**.

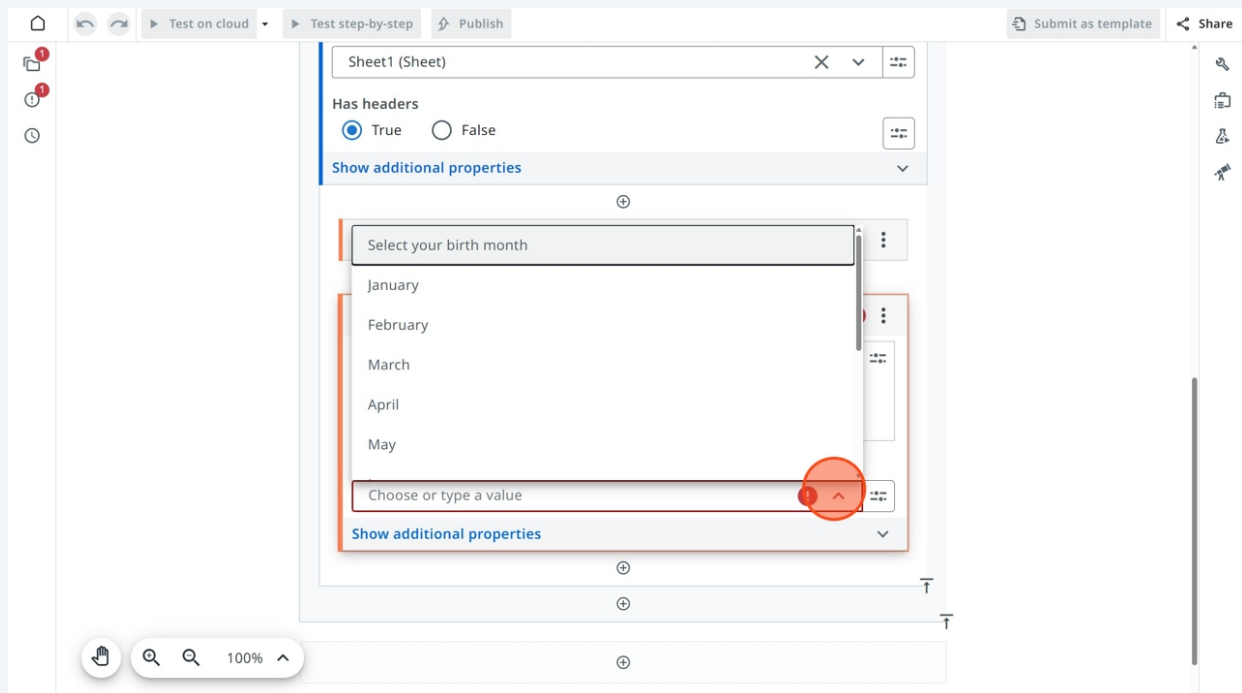

23 Indicate the **Birth Month** dropdown and confirm your selection.

24

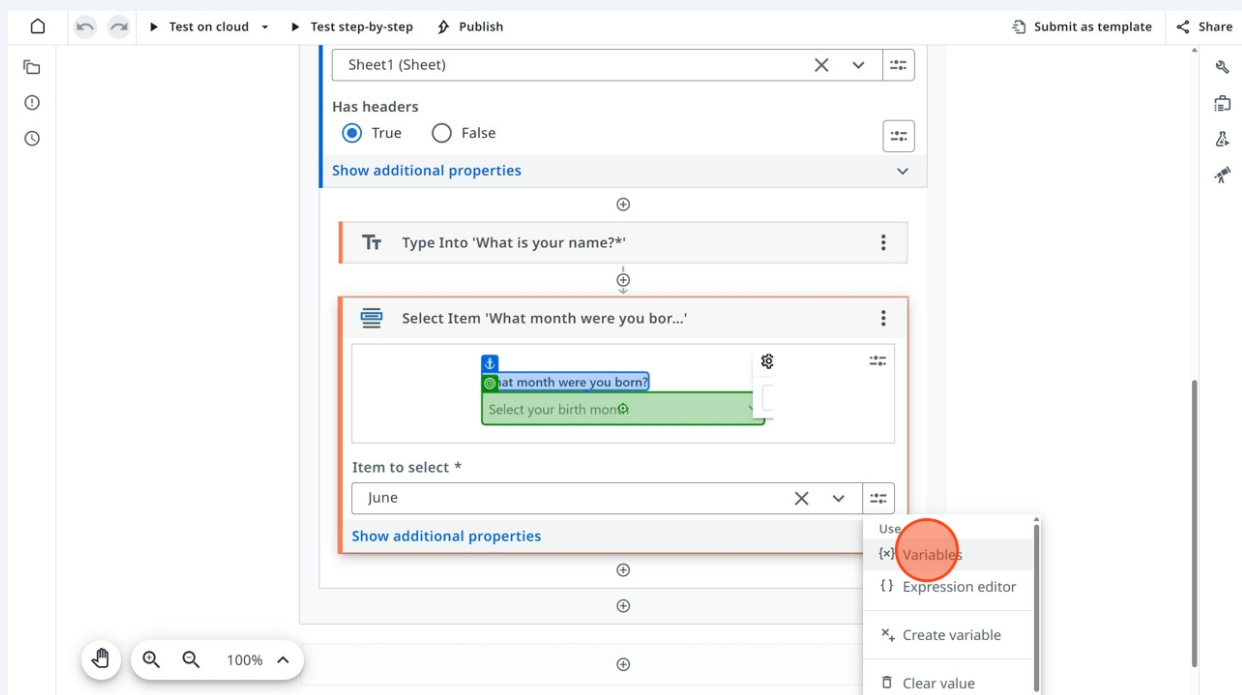

The values currently shown in the **Item to select** field were captured from the website.

We need to replace that with the **Month** value from the spreadsheet.

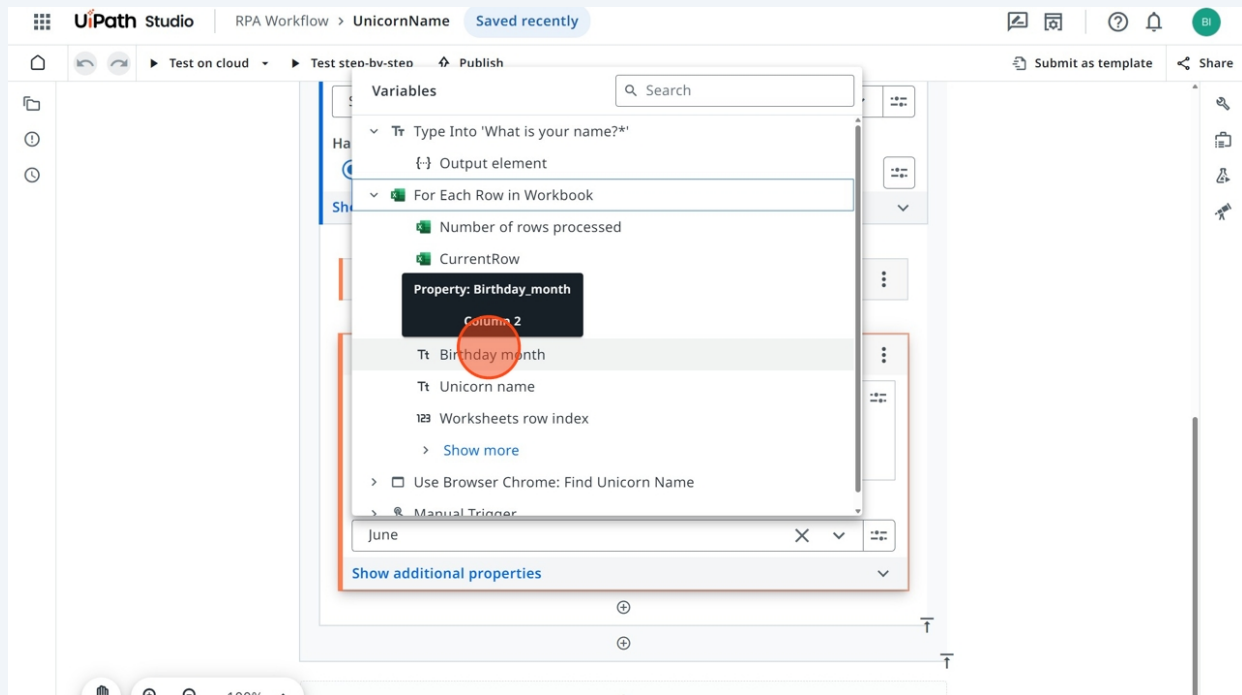

25

Open the menu on the right side of the field and select **Variables**.

26

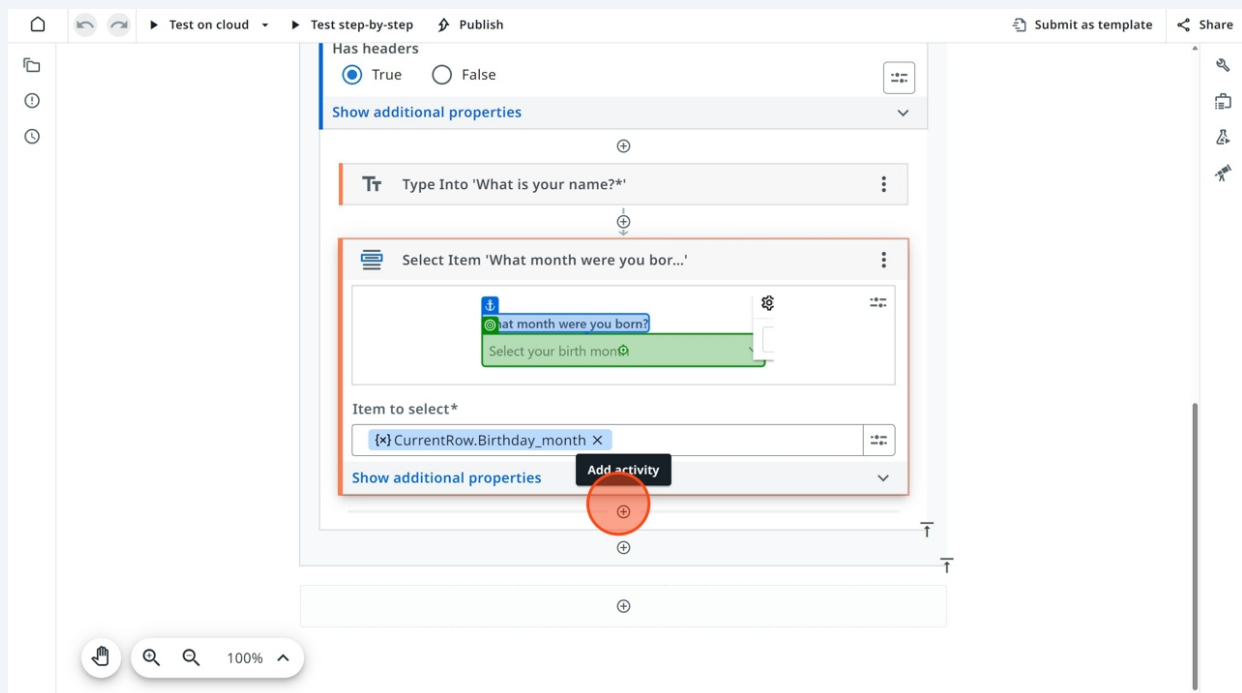

Now, select the **Birthday Month** variable listed under **For Each Row in Workbook**.

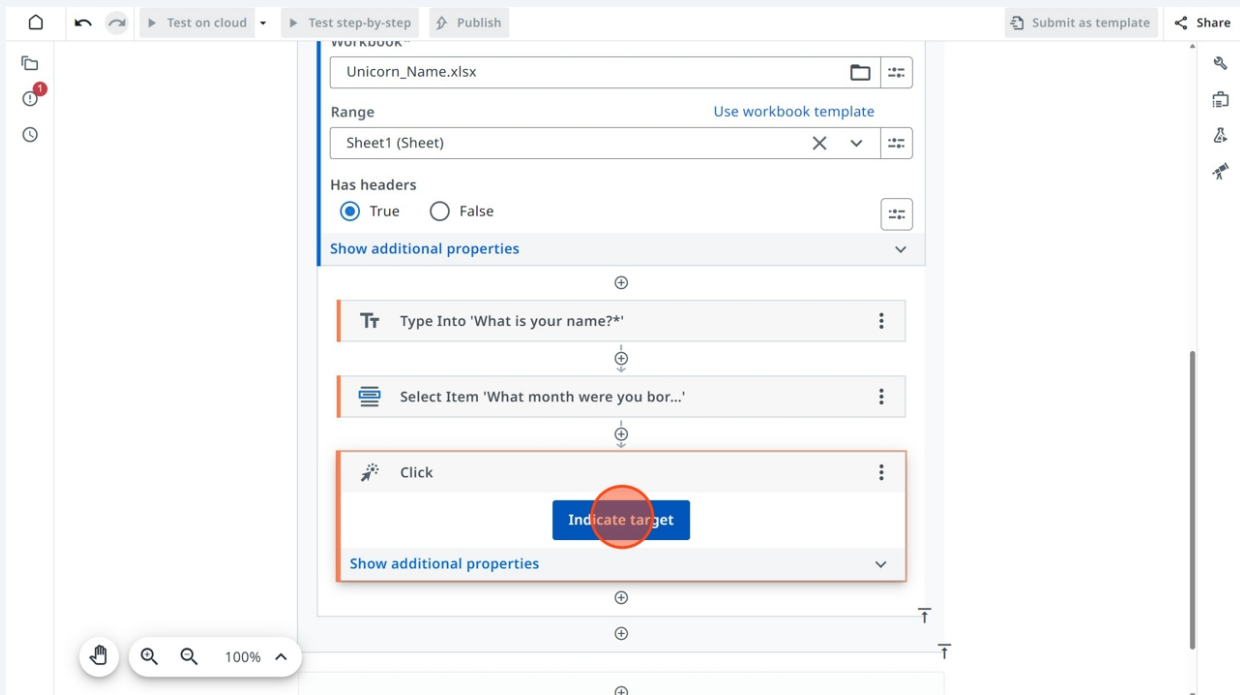

27

The last step before testing is to click the **Get Unicorn Name** button.

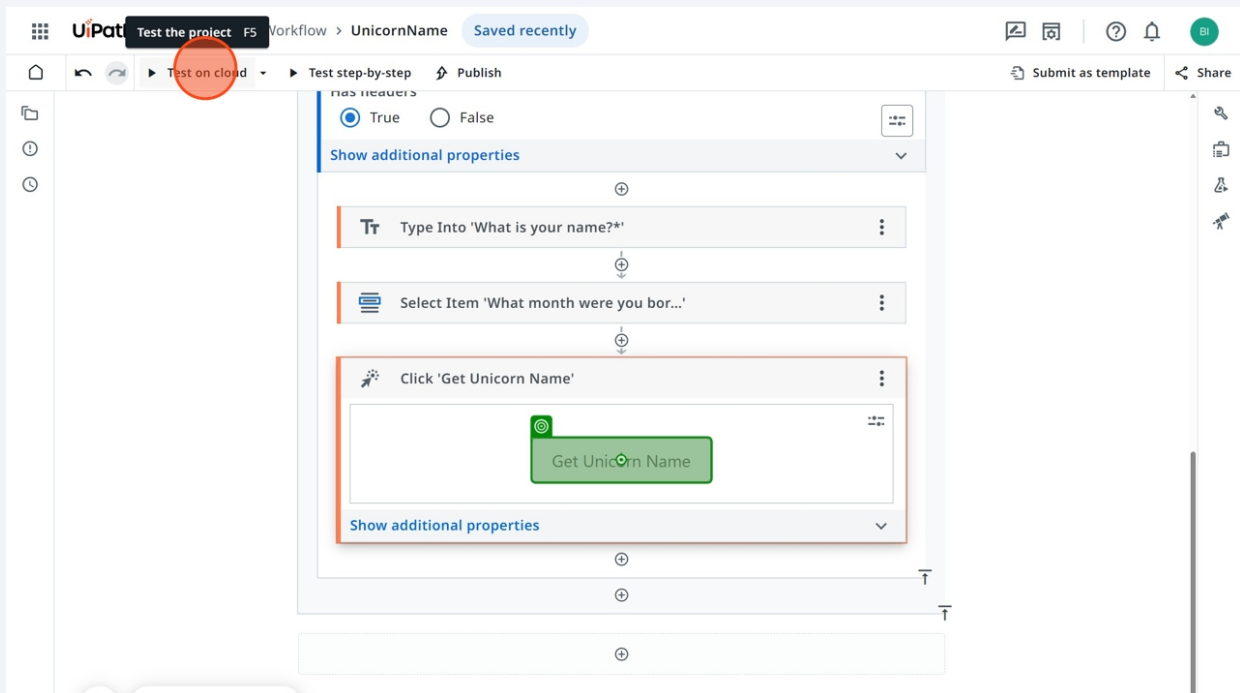

Add a **Click** activity to perform this action.

28 Click **Indicate Target**, then select the **Get Unicorn Name** button.

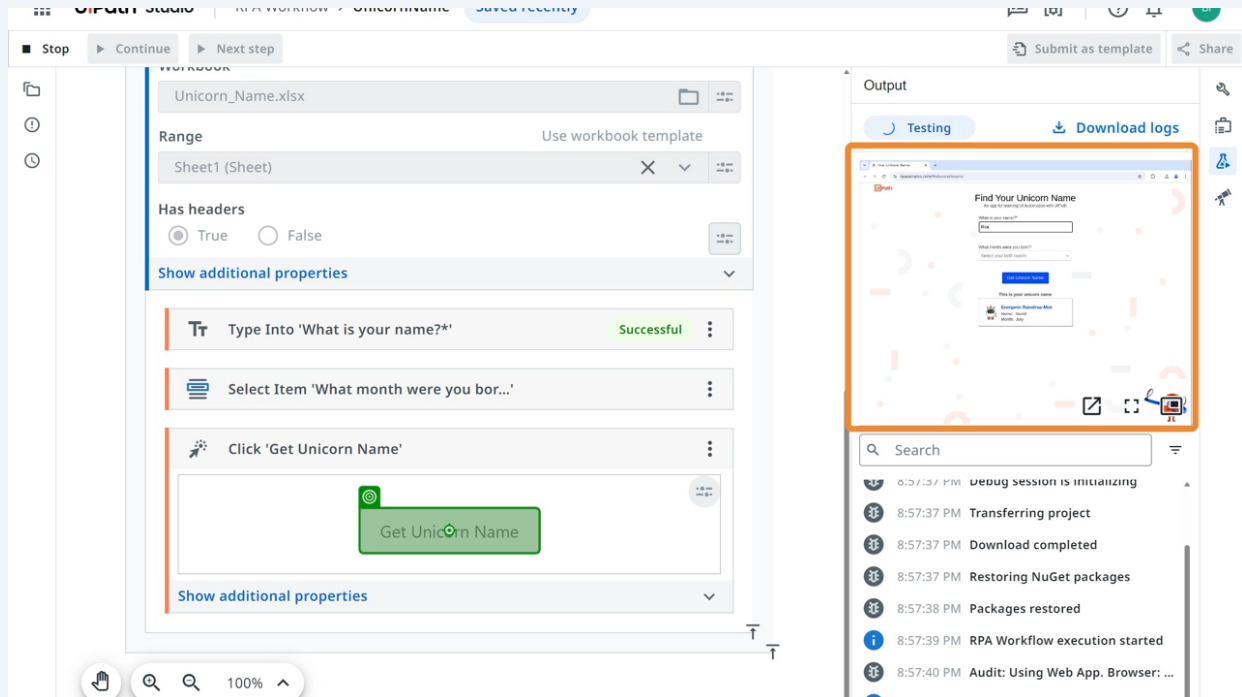

29 It's time to **test** what you've built so far!

30

This screen gives you a live visual preview of what the robot is doing during the test. This helps you:

- Confirm the robot is targeting the right elements
- Spot errors or misaligned UI actions
- Troubleshoot issues quickly

31

If your execution was successful, it's time to add the final activity for the form automation—**Get Text**.

The screenshot displays the UiPath Studio interface. On the left, the workflow editor shows a sequence of three activities: 'Type Into' (with text 'What is your name?'), 'Select Item' (with text 'What month were you born?'), and 'Click' (with text 'Get Unicorn Name'). The 'Click' activity is selected, and the 'Add activity' button is highlighted with a red circle. On the right, the Output window shows the execution log, indicating that the RPA Workflow execution ended successfully at 8:57:54 PM.

32

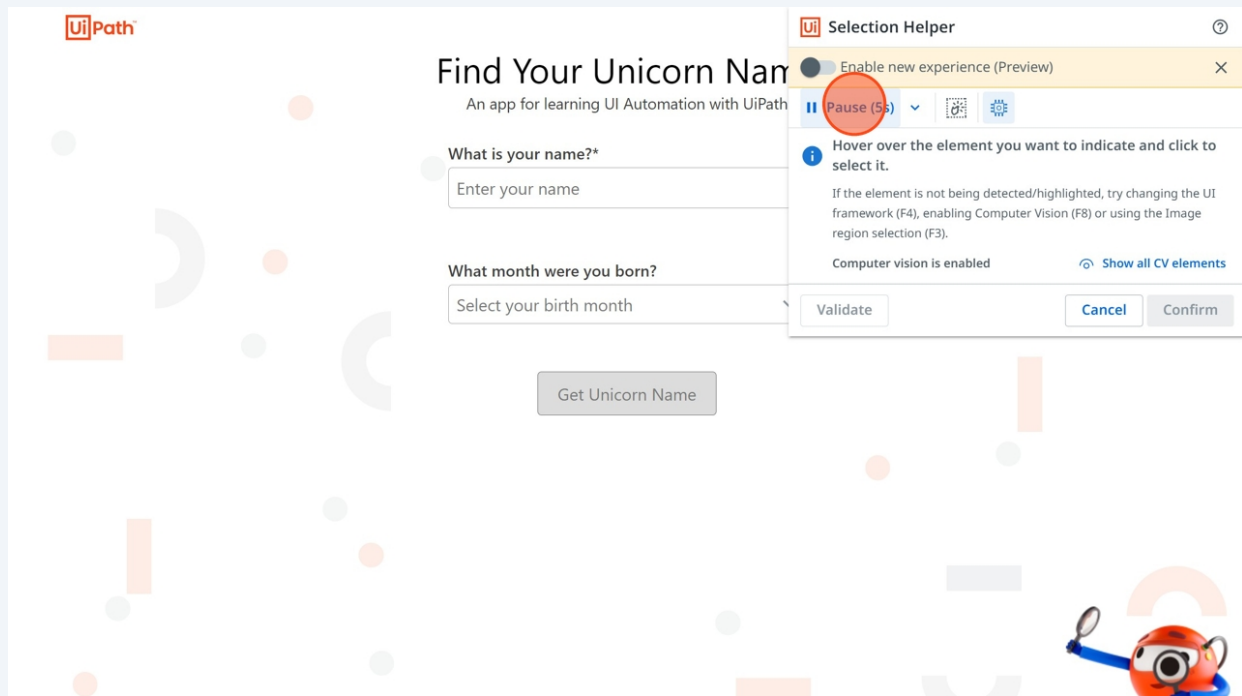

Click **Indicate target**.

The screenshot displays the UiPath Studio interface. On the left, the workflow editor shows a sequence of three activities: 'Type Into' (with text 'What is your name?'), 'Select Item' (with text 'What month were you born?'), and 'Click' (with text 'Get Unicorn Name'). The 'Click' activity is selected, and the 'Indicate target' button is highlighted with a red circle. On the right, the Output window shows the execution log, indicating that the RPA Workflow execution ended successfully at 8:57:54 PM.

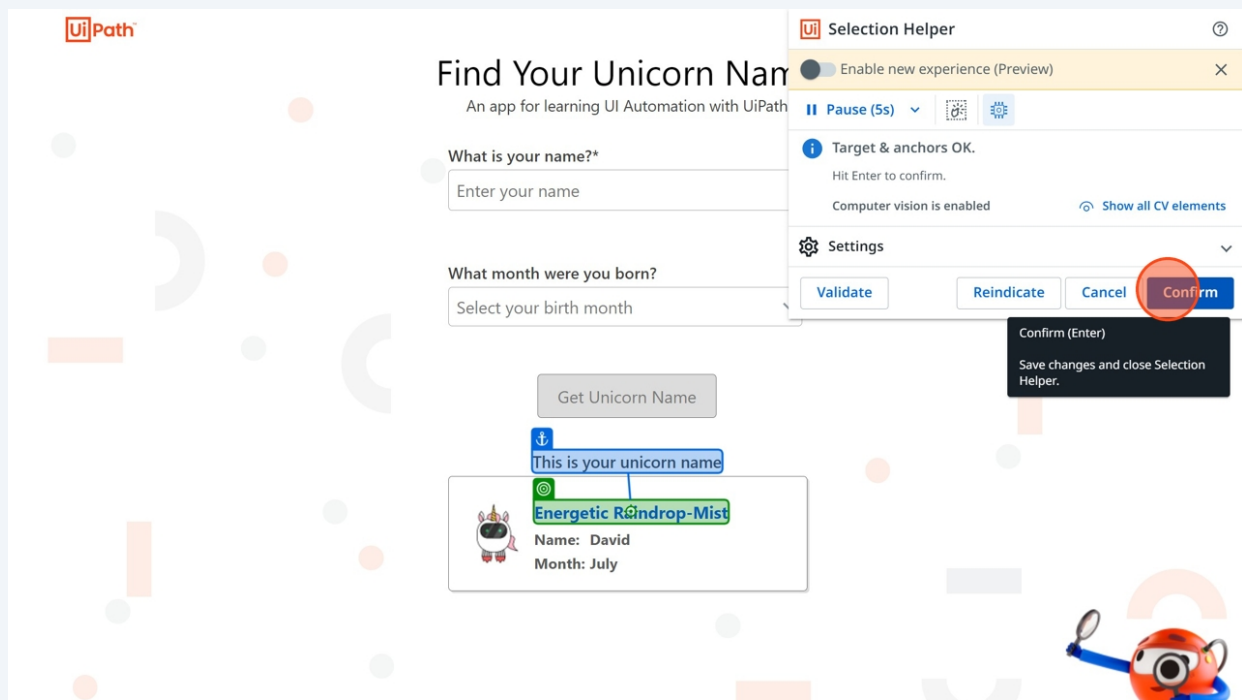

33 Notice that the generated name doesn't appear right away.

Click **Pause** to delay the target selection for a few seconds. Then, enter some random data to activate the **Get Unicorn Name** button so you can click it.

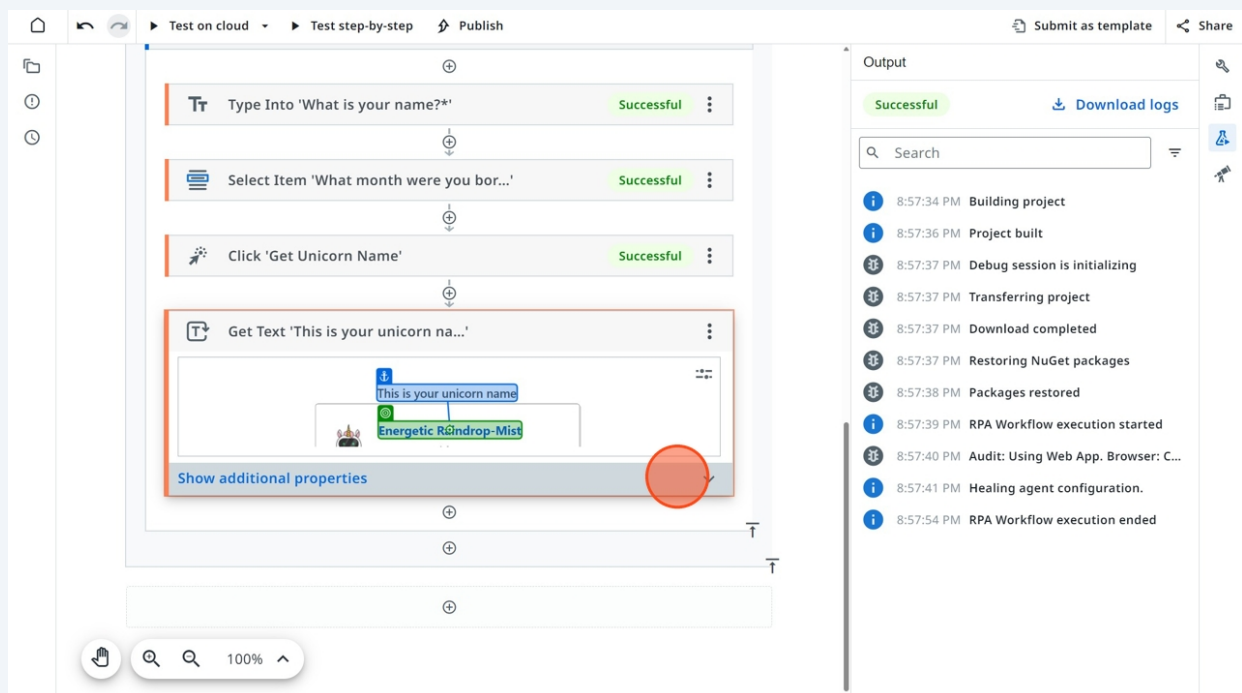

Don't worry if you need more time—you can extend the pause or delete and retry any unwanted targets.

34 Select the generated value and confirm the selection.

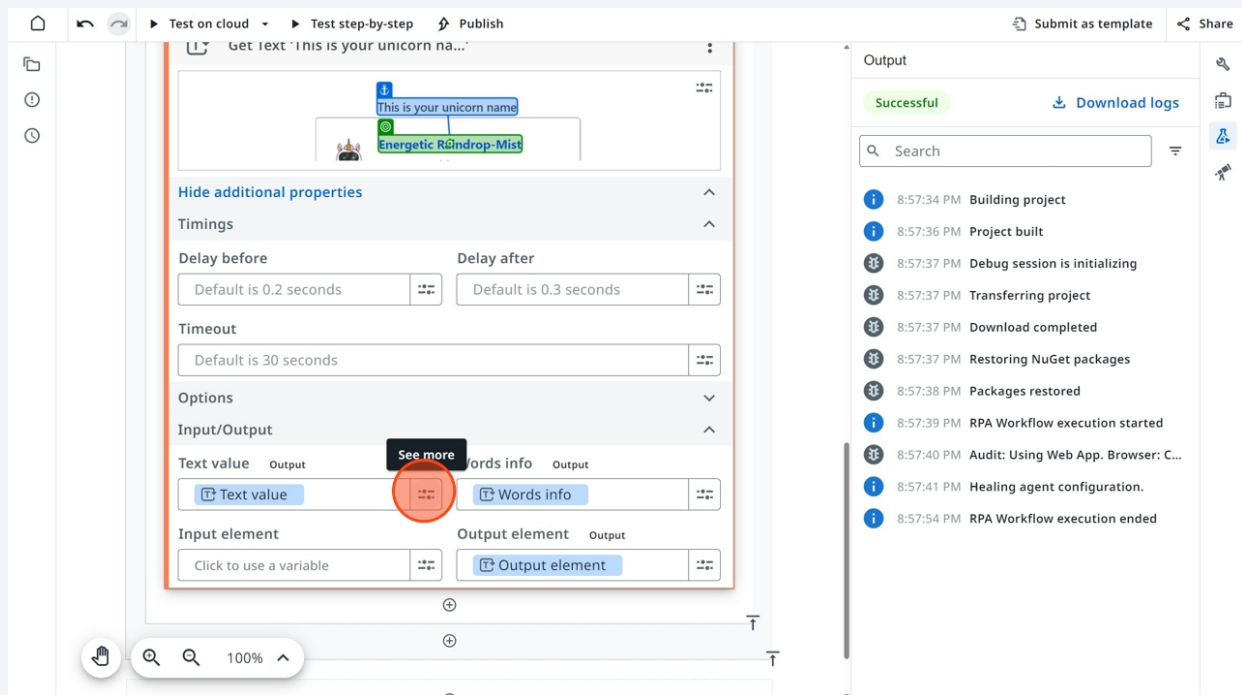

35 Click "Hide additional properties"

36

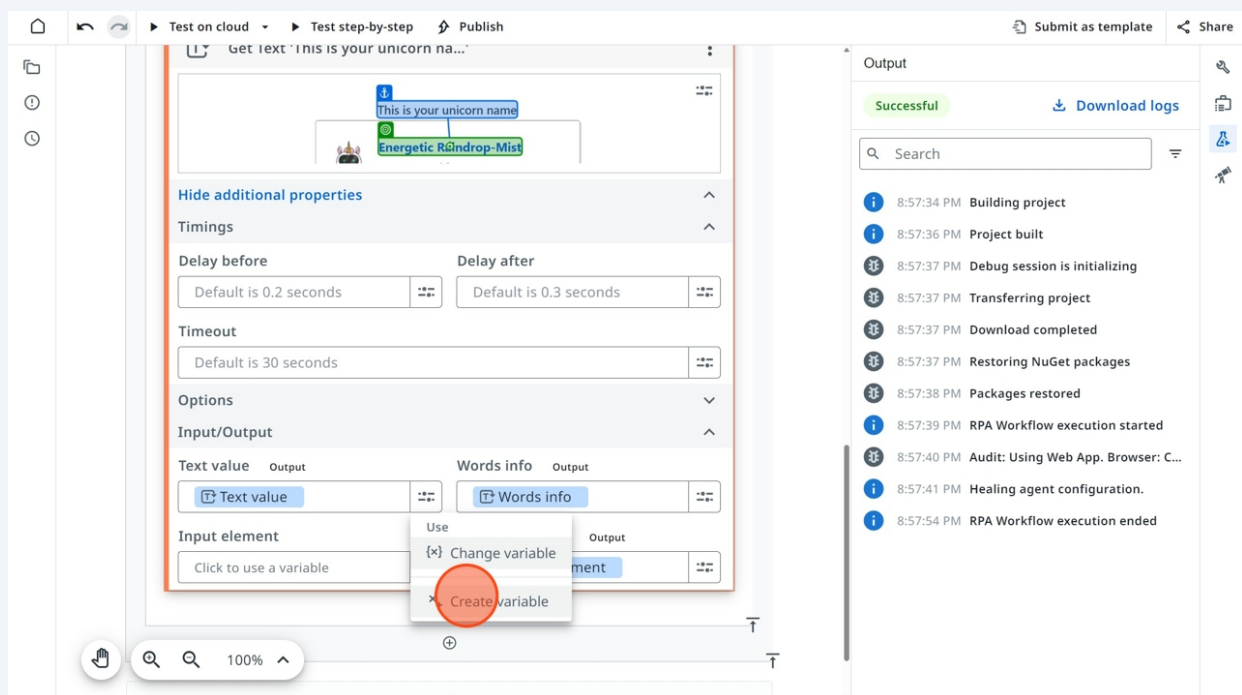

Let's open the **additional settings** of the **Get Text** activity and create a new variable to store the extracted value.

This will make it easier to identify and use the correct variable in the next activity.

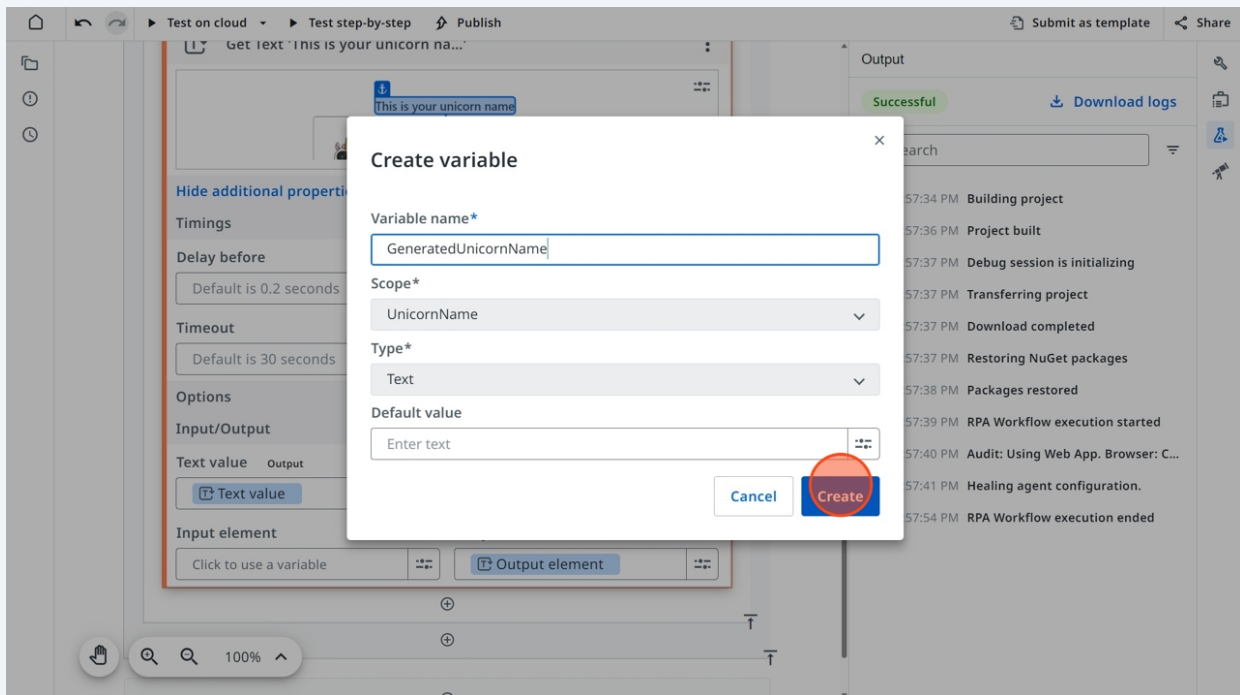

37

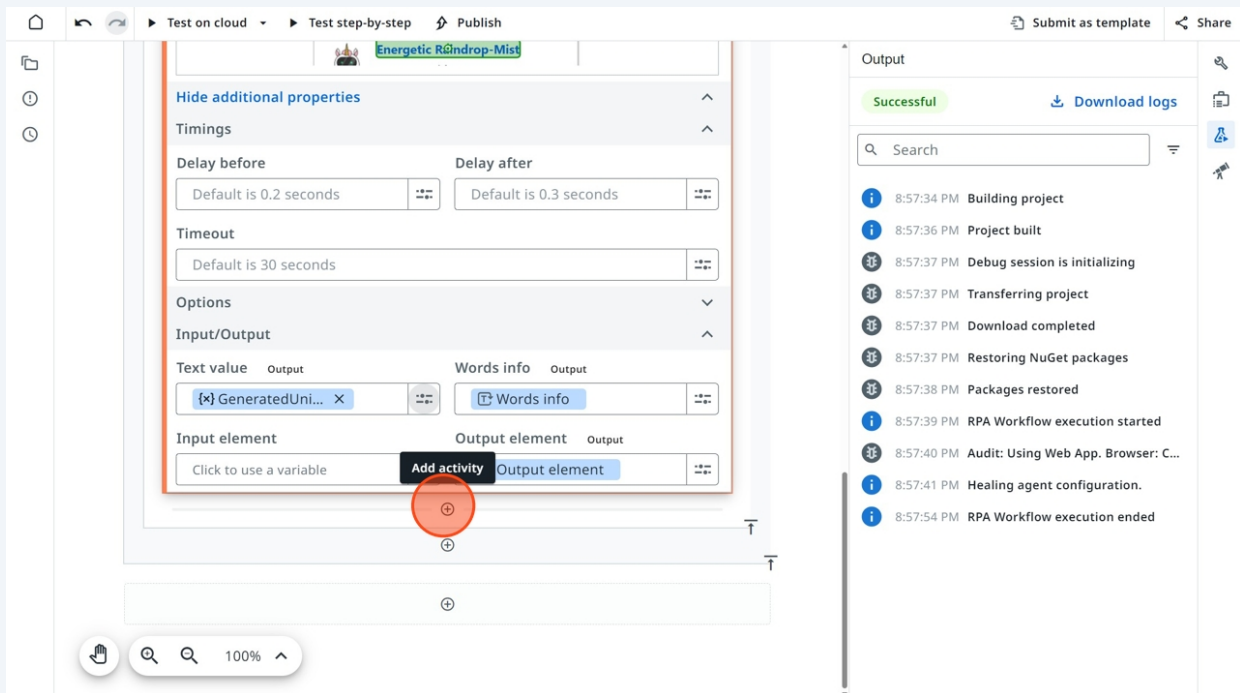

Open the menu next to **Text value** and select **Create variable**.

38 Rename it to **GeneratedUnicornName**, and click **Create**.

39 The final step in this part of the exercise is to **write the extracted value back into the spreadsheet**. Add the **Write Cell** activity.

40

To configure the activity:

- Select the **Unicorn_Name** file again.
- Choose the **Sheet1** range.
- Under **Cell**, search for the **Unicorn name Address** variable from the **For Each Row in Workbook** section.
- In the **What to write** field, select the **GeneratedUnicornName** variable.

The screenshot shows the configuration of a 'Write Cell' activity within a Power Automate flow. The activity is connected to a 'For Each Row in Workbook' loop. The configuration fields are as follows:

- Microsoft OneDrive & SharePoint connection ***: #2 [default]
- Workbook***: Unicorn_Name.xlsx
- Sheet or named range ***: Sheet1
- Cell**: {x} CurrentRow.Unicorn_name_Address
- What to write ***: {x} GeneratedUnicornName

Above the 'Write Cell' activity, there are input and output elements for 'Text value' and 'Words info'. The 'Text value' input element is set to {x} GeneratedUni... and the 'Words info' output element is set to Words info. The 'Output element' is set to Output element.

How to send a file via email

41

Last part of the exercise is to email the processed file. **Outside** the Use Browser, add the **Send email** activity.

The screenshot displays the UiPath Studio interface for an RPA workflow named 'UnicornName'. The workflow is saved recently and is currently in the 'Test on cloud' mode. The workflow consists of two activities: a 'Manual Trigger' and a 'Use Browser Chrome: Find Unicorn Name' activity, both marked as 'Successful'. A red circle highlights the 'Add activity' button below the second activity. The right pane shows the 'Output' window with a list of execution logs.

Output Log:

- 8:57:34 PM Building project
- 8:57:36 PM Project built
- 8:57:37 PM Debug session is initializing
- 8:57:37 PM Transferring project
- 8:57:37 PM Download completed
- 8:57:37 PM Restoring NuGet packages
- 8:57:38 PM Packages restored
- 8:57:39 PM RPA Workflow execution started
- 8:57:40 PM Audit: Using Web App. Browser: C...
- 8:57:41 PM Healing agent configuration.
- 8:57:54 PM RPA Workflow execution ended

42

Configure the activity to send the email to automation-first@uipath.com (Just type it in).

For the email **Subject** type in "Unicorn name exercise".

For the **Body** field, use the following message:

"If you're getting this email, then my first automation in Studio Web was successful! Here's the Unicorn Name workbook you requested."

Search

8:57:34 F
 8:57:36 F
 8:57:37 F
 8:57:37 F
 8:57:37 F
 8:57:37 F
 8:57:38 F
 8:57:39 F
 8:57:40 F
 8:57:41 F
 8:57:54 F

You'll notice that you **cannot select** any file to use as an attachment.

In Studio Web, when you create or process a file (like an Excel spreadsheet), it's often stored **in the cloud temporarily** — not on your local device or in a format that's ready to send.

To attach it to an email, the robot needs to:

- **Download** the file to a real, accessible location (like your Downloads folder or a known path)
- Use that downloaded file as the attachment

This step ensures the file has a **physical, accessible path**, which the email activity needs to locate and attach it properly.

43 Add the **Download File** activity before the **Send Email** activity.

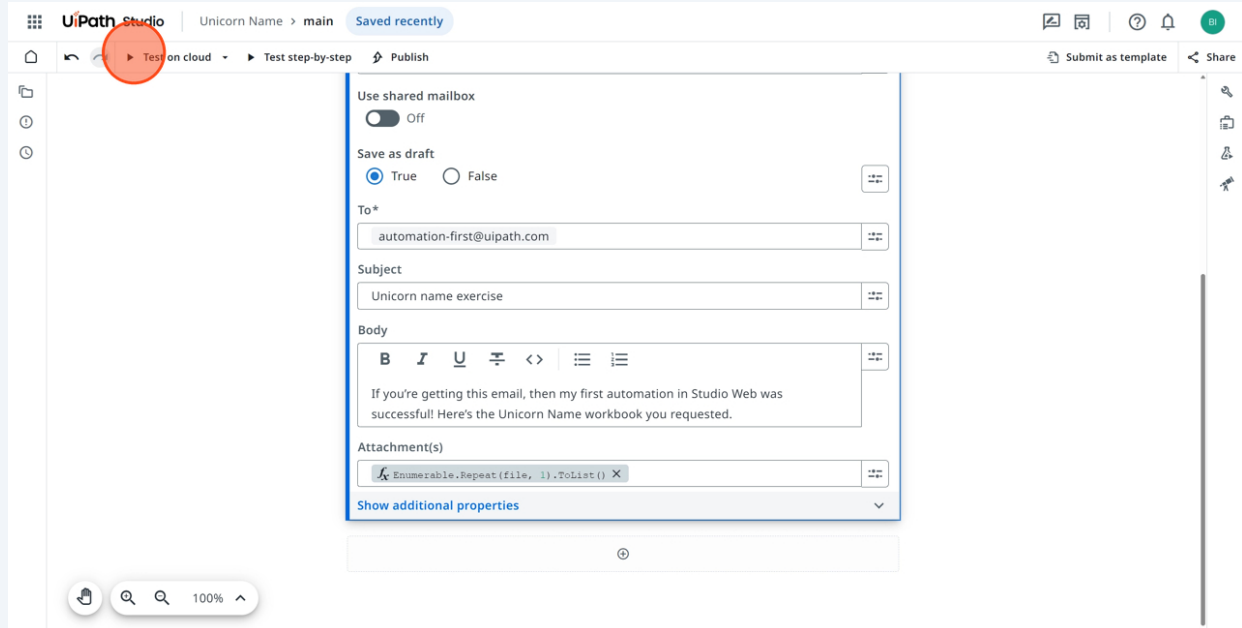

Select the **Unicorn_Name** file as the file to download.

The screenshot shows the UiPath Studio interface with a workflow named 'UnicornName'. The workflow consists of three activities: 'Manual Trigger', 'Use Browser Chrome: Find Unicorn Name', and 'Download File'. The 'Download File' activity is highlighted with a red circle. The 'Send Email' activity is positioned below it. The 'Download File' activity's 'File to download*' field is also highlighted with a red circle. The 'Output' pane on the right shows a successful execution log.

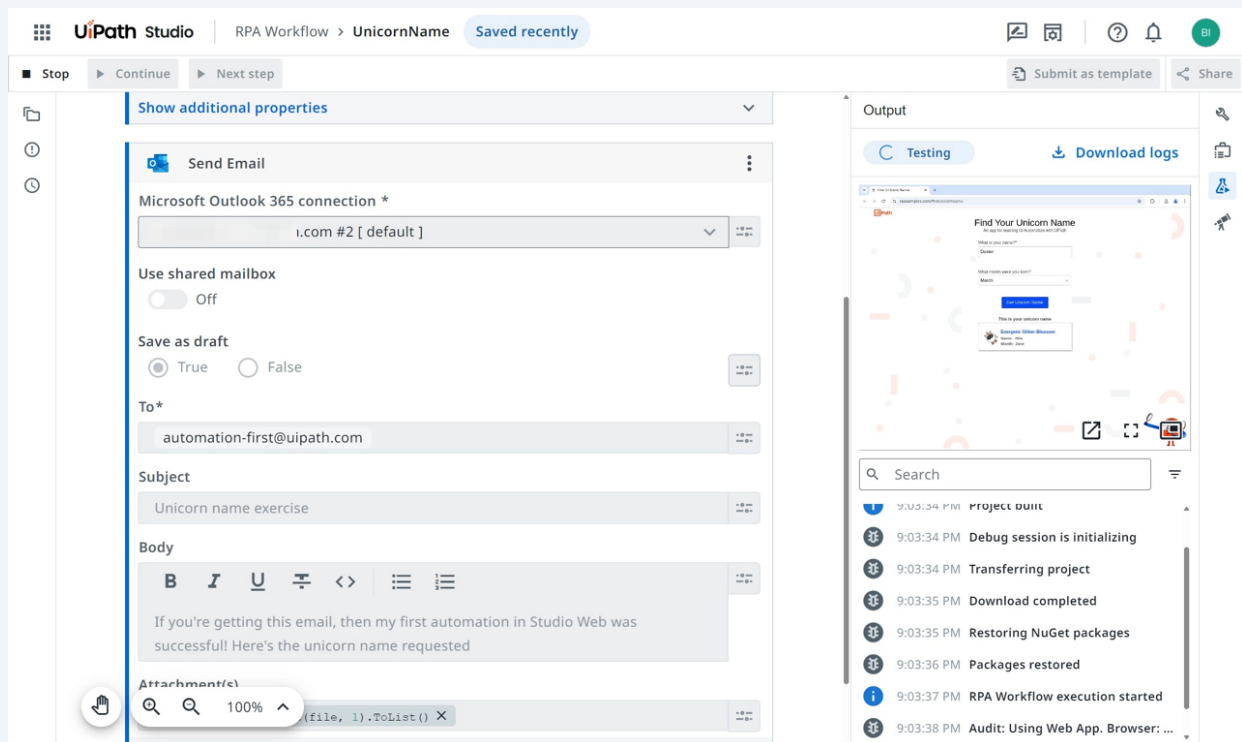

44 Now, go back to the **Send Email** activity and select the **File** variable from the **Downloaded File** activity to use as your email attachment.

The screenshot shows the 'Send Email' activity in the workflow editor. The 'Use shared mailbox' toggle is turned off. The 'Attachment' dropdown menu is open, showing a list of variables. The 'File' variable is highlighted with a red circle. The 'Output' pane on the right shows a successful execution log.

45 Time to do a **final test**!

46 When the execution finishes, check your **Drafts** folder. You'll find the email created by the automation, with the processed file attached.

47

Finished!
